Association of risk factors for cervical cancer and human papilloma viruses in invasive cervical cancer

M. Uršič-Vrščaj[1], J. Kovačič[2], M. Poljak[3], J. Marin

Institute of Oncology, Ljubljana, Slovenia; University Department of Gynecology and Obstetrics, Ljubljana, Slovenia; Institute of Microbiology, Faculty of Medicine, Ljubljana, Slovenia

Received January 29, 1996; revised manuscript accepted for publication March 11, 1996

Summary

Our study was carried out on 70 patients with invasive squamous carcinoma of the uterine cervix (CC) or invasive adenocarcinoma of the uterine cervix at all stages, admitted to the University Department of Gynecology and/or to the Institute of Oncology in Ljubljana. The patients were not selected by age. A questionnaire on known risk factors in CC was filled in for each of the 70 patients, and two tumor smears were taken for the determination of human papilloma viruses (HPV) 16 and 18 by means of *in situ* hybridization and polymerase chain reaction (PCR). Each patient also had the serum level of vitamin A determined. The results of our study revealed a correlation between HPV 16 or 18 infection (60:40) and CC. When analysing some already known risk factors, no statistically significant difference could be established for any of the factors studied, except for the age at first birth.

Key words: Invasive carcinoma of the uterine cervix; Human papilloma viruses 16 and 18, in situ hybridization; Polymerase chain reaction; Risk factors for cervical cancer.

Cepljenje proti raku na maternicnem vratu

Občinski svet občine Komenda je sprejel predlog župana **Tomaža Drolca**, da 1,5 milijona tolarjev namenijo cepljenju deklet v osmem in devetem razredu osnovne šole proti virusu, ki povzroča raka na maternicnem vratu. V občini Komenda je deklet v tej starosti okrog 50. Njim in njihovim staršem bodo jutri na okrogli mizi pojasnili vse o virusu, bolezni in novem cepivu. Ker je cepivo precej drago, so se v občini odločili, da bodo naprej zagotovili možnost cepljenja dekletom, ki bodo prihodnje leto šla v srednjo šolo in tako zapustila občino. Kasneje obstaja možnost, da bi cepljenje omogočili tudi drugim. V roku petih ali sedmih let naj to cepljenje ne bi bilo več samoplačniško in naj bi ga krila zdravstvena blagajna oziroma zdravstveno zavarovanje.

Cepivo deluje na dva virusa, ki ju povezujejo s tem rakom, in naj bi ženske vsaj za nekaj časa varovalo pred izbruhom bolezni. Namenjeno je zlasti dekletom do 26. leta. Pri tem velja, da je najboljši čas za cepljenje pred prvim spolnim odnosom. Cepljenje proti omenjenem virusu naj bi sicer še v tem mesecu v Sloveniji postalo dostopno vsem samoplačnikom, odločitev komendskih svetnikov, da za cepljenje namenijo občinski denar, pa je prva v Sloveniji. **(sta)**

I have no conflicts of interest to declare.

cervical cancer is at present the best (and only) human cancer candidate for eradication

...

because it is a result of infectious disease

...

but, elimination is more realistic goal

ERADICATION

No single case of particular disease in the whole world in the last 5 years

ERADICATION

a permanent reduction to zero of the worldwide incidence of infection

intervention measures are no longer needed

ELIMINATION

achieving the measurable global targets set by WHO

control measures must be continued after elimination has been achieved

Human diseases with greatest potential for eradication

Guinea worm
Lymphatic filariasis
River blindness

Polio

Measles
Mumps
Rubella

Cervical cancer as best human cancer candidate for elimination

important public health issue (569'847 cases per year; 311'365 deaths)
GLOBOCAN 2018

infectious origin, no reservoirs outside humans

long clinical latency

acceptable and valid screening tools available

precursors lesions can be treated in a safe, effective and acceptable way

safe and effective vaccines against main etiological factor - HPV

WHO statement on cervical cancer elimination Director-General call to action

World Health Organization

"Today I am calling for coordinated action globally to eliminate cervical cancer, one of the greatest threats to women's health. We have the tools and, crucially, the political commitment to achieve it"

www.who.int/reproductivehealth/DG_all-to-action.pdf

Preventable fractions of cervical cancer via effective screening in six Baltic, central, and eastern European countries 2017–40: a population-based study

Salvatore Vaccarella, Silvia Franceschi, David Zaridze, Mario Poljak, Piret Veerus, Martyn Plummer, Freddie Bray

Lancet Oncol 2016; 17: 1445-1452

Summary

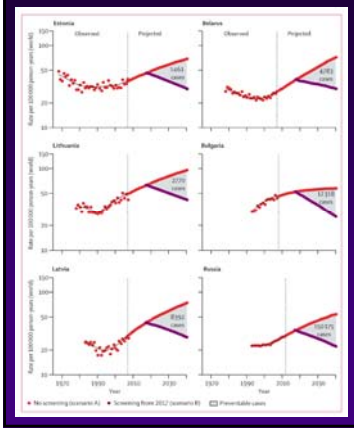
Background Cervical cancer incidence remains high in several Baltic, central, and eastern European (BCEE) countries, mainly as a result of a historical absence of effective screening programmes. As a catalyst for action, we aimed to estimate the number of women who could be spared from cervical cancer across six countries in the region during the next 25 years, if effective screening interventions were introduced.

Methods In this population-based study, we applied age-period-cohort models with spline functions within a Bayesian framework to incidence data from six BCEE countries (Estonia, Latvia, Lithuania, Belarus, Bulgaria, and Russia) to develop projections of the future number of new cases of cervical cancer from 2017 to 2040 based on two future scenarios: continued absence of screening (scenario A) versus the introduction of effective screening from 2017 onwards (scenario B). The timespan of available data varied from 16 years in Bulgaria to 40 years in Estonia. Projected rates up to 2040 were obtained in scenario A by extrapolating cohort-specific trends, a marker of changing risk of human papillomavirus (HPV) infection, assuming a continued absence of effective screening in future years. Scenario B added the effect of gradual introduction of screening in each country, under the assumption period effects would be equivalent to the decreasing trend by calendar year seen in Denmark (our comparator country) since the progressive regional introduction of screening from the late 1960s.

Findings According to scenario A, projected incidence rates will continue to increase substantially in many BCEE countries. Very high age-standardised rates of cervical cancer are predicted in Lithuania, Latvia, Belarus, and Estonia (up to 88 cases per 100 000). According to scenario B, the beneficial effects of effective screening will increase progressively over time, leading to a 50–60% reduction of the projected incidence rates by around 2040, resulting in the prevention of cervical cancer in 1500 women in Estonia and more than 150 000 women in Russia. The immediate launch of effective screening programmes could prevent almost 180 000 new cervical cancer diagnoses in a 25-year period in the six BCEE countries studied.

Interpretation Based on our findings, there is a clear need to begin cervical screening in these six countries as soon as possible to reduce the high and increasing incidence of cervical cancer over the next decades.

Observed and projected incidence of cervical cancer in six Baltic, central, and eastern European countries (2017-2040)



if screening had started in 2017 more than 180,000 new cases of cervical cancer could have been prevented from 2017 to 2040 in the six studied countries

HPV !!!

HPV test ?

HPV-based primary cervical cancer screening

PRO:

- more sensitive than cytology to detect CIN2+, CIN3+ and cervical cancer
- more accurate and less variable than cytology
- risk of CIN2+ in women who are HPV negative is substantially lower than in women who are cytologically negative = extension of screening intervals possible and safe
- possibility of self-sampling testing

CON:

- reduced specificity of HPV DNA testing requires appropriate triage

Papillomavirus Research 2015; doi:10.1016/j.pvr.2015.06.006.

European guidelines for quality assurance in cervical cancer screening. Summary of the supplements on HPV screening and vaccination

HPV test choice

cervical cancer screening program should adopt a HPV primary test for use only if it has been validated by demonstrating reproducible, consistently high sensitivity for CIN2+ and CIN3+ lesions, and only minimal detection of clinically irrelevant, transient HPV infection

HPV tests (neither commercial nor in-house tests) that have not been clinically validated should not be used in clinical practice

secondary & primary prevention

Requirements for HPV tests in primary cervical screening

1. A clinical sensitivity for CIN2+ not less than 90% of the clinical sensitivity of the hc2 in women of at least 30 years.

2. A clinical specificity for CIN2+ not less than 98% of the clinical specificity of the hc2 in women of at least 30 years of age.

3. Intra-laboratory reproducibility and inter-laboratory agreement with a lower confidence bound not less than 87%.

VALGENT 2
6 HPV assays - samples derived from Scottish HPV archive

VALGENT 3
14 HPV assays – samples derived from Slovenian national cohort

VALGENT 4
11 HPV assays – samples from Copenhagen, Denmark

Issues to be resolved…

we need complete HPV diagnostic assays including sample extraction procedure !

manufacturers should put more effort into evaluating their HPV products

manufacturers should seek advice from established HPV researchers in the very early phase of development on:
- how to properly design a novel test
- define intended use of future test (clinical, epidemiological, research…)
- how to evaluate test performance that the HPV community will accept evaluation/validation results

manufacturer-independent evaluations and publication of results in peer-reviewed journals are crucial

evaluation on alternative clinical specimens needed (self-collected cervicovaginal lavage specimens, vaginal swabs, other self-collected samples, tissues, urine…)

more competitively priced HPV tests needed !

Which high-risk HPV assays fulfil criteria for use in primary cervical cancer screening?

200 Million Monthly COVID-19 Tests Needed in US, Report Says

Sep 09, 2020 | staff reporter

Save for later

NEW YORK – To open safely and in stages, a US nationwide screening strategy will require about 200 million tests each month for students and staff at the nation's primary and secondary schools, as well as residents and staff at nursing homes, according to a report released on Wednesday.

UK Government Unveils Plan to Run 500,000 COVID-19 Tests Per Day

Sep 10, 2020 | staff reporter

Save for later

NEW YORK – The UK government plans to ramp testing for SARS-CoV-2 to half a million kits processed per day by the end of October in a bid to reopen the country after months of social distancing measures to control the virus, which causes the disease COVID-19.

COVID-19-related problems arising

- unprecedented health and economic impact of the COVID-19 pandemic
- due to the COVID-19 pandemic, cervical cancer prevention activities have been disrupted in many countries; in May 2020, 46% of the 122 countries included in a WHO survey report closure of population-level screening activities; ICSN found that cancer screening services were suspended in 88% of the settings
- extraordinary demand on a global scale for sampling devices, reagents, consumables, and diagnostic instruments needed for timely diagnosis of SARS-CoV-2 infection
- manufacturer's shift toward new niche market with unprecedented market growth opportunity
- serious COVID-19-related supply chain problems (reagents and consumables)
- preexisting microbiology lab employee shortage, then COVID-19 pandemic hit
- shifted interest of public, agencies and medical journals ("nothing is important but COVID-19")
- "new normal"; unclear future; potential of second, third, fourth… waves of pandemic

Panther (Hologic)

about 1,100 instruments across U.S.

at full tilt, the machines could process about 33 million tests per month, but the company makes roughly 4.8 million

only clinically validated HPV tests should be used in cervical cancer screening

PQDx 0268-070-00 WHO PQ Public Report December 2017/ version 3.0

WHO Prequalification of In Vitro Diagnostics
PUBLIC REPORT

Product: Xpert® HPV
WHO reference number: PQDx 0268-070-00

Xpert® HPV with product code **GXHPV-CE-10** manufactured by **Cepheid AB, CE marked regulatory version**, was accepted for the WHO list of prequalified in vitro diagnostics and was listed on 21 December 2017.

Intended use:
The Xpert® HPV assay is a qualitative in vitro test for the detection of the E6/E7 region of the viral DNA genome from high risk Human Papillomavirus (HPV) in patient specimens. The test carries out multiplexed amplification of target DNA by real-time Polymerase Chain Reaction (PCR) of 14 high risk HPV types in a single analysis. Xpert® HPV specifically identifies types HPV 16 and HPV 18/45 in two distinct detection channels, and reports 11 other high risk types (31, 33, 35, 39, 51, 52, 56, 58, 59, 66 and 68) in a pooled result. Specimens are limited to cervical cells collected in PreservCyt® Solution (Hologic Corp.). Cervical specimens collected in PreservCyt Solution that have been pretreated with Glacial Acetic Acid (GAA) to lyse excess red blood cells for cytology review have also been validated for use with the Xpert® HPV assay.

Conclusions (secondary prevention)

254+ commercial HPV assays (and 425+ variants) on the global market

60% of HPV tests on the global market without a single peer-reviewed publication

81% of HPV tests on the market without published performance evaluation (analytical and/or clinical) in peer-reviewed journals

great majority of performance evaluations not in line with standards agreed in the HPV community

several clinically unvalidated HPV assays are used worldwide in daily practice - only a small subset of HPV tests on the market has validated clinical performance

2 + 11 HPV assays fulfil cross-sectional criteria for primary screening

2 + 3 HPV assays have at least 36+ months longitudinal data

serious COVID-19-related supply chain problems arising

COVID-19 pandemic's negative impact on cancer control creates the opportunity to make self-sampling a standard to empower women everywhere

Elimination definition and 2030 targets

Vision: A world without cervical cancer

Goal: cervical cancer incidence below 4 cases per 100,000 woman-years

2030 TARGETS

90% of girls fully vaccinated against HPV by age 15

70% of women screened with a high precision test at ages 35 and 45

90% of women with cervical disease receive treatment and care

2030 target: 30% reduction in mortality from cervical cancer

100 Countries Included HPV Vaccine in the National Immunization Program (Nov 2019)

98-100% efficacy against anogenital lesions (cervical, vulvar, vaginal, and anal) caused by targeted HPV types in several large international randomized, double-blind trials

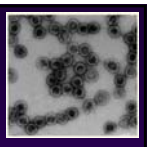
CLINICAL GUIDELINE

Recommended Immunization Schedule for Adults Aged 19 Years or Older, United States, 2017*

Two doses are recommended for persons starting the series before their 15th birthday.

Three doses are recommended for those who start the series on or after their 15th birthday and for persons with certain immunocompromising conditions.

Prophylactic HPV vaccines



L1 viral like particles

2vHPV: 16 and 18 with AS04

4vHPV: 6, 11, 16 and 18 with aluminium

9vHPV: 6, 11, 16, 18, 31, 33, 45, 52 and 58 with aluminium

Randomized controlled efficacy trial in Costa Rica to test efficacy of 1 dose vs. 2 doses (NCI & Gates Foundation)

4-arm non-inferiority trial in 12-16 year old girls:

- 1 dose and 2 doses of bivalent vaccine and 9-valent vaccine
- unethical to have a placebo arm

Main hypothesis:

- protection induced by 1 dose is not inferior to 2 doses

Second hypothesis:

- protection will be similar for 1 dose of either vaccine
- potential difference due to adjuvant: alum vs. AS04

clinicaltrials.gov: identifier NCT03180034

Avis sur le calendrier de vaccination contre les virus du papillome humain (VPH)

Dépôt légal – 2e trimestre 2018

COMITÉ SUR L'IMMUNISATION DU QUÉBEC

a two-vaccine mixed schedule:
- one dose of 9v vaccine followed by one dose of 2v vaccine

rationale: to maximize the immune response against HPV-16 and HPV-18 while ensuring good immunity against the other seven HPV types included in 9v-vaccine

only for girls and boys aged 9 to 17 years in good health

for individuals aged 18 and over as well as for other groups (e.g. immunocompromised), the vaccination schedule remains unchanged (2 doses of 9v vaccine)

Has Human Papillomavirus (HPV) Vaccination Prevented Adverse Pregnancy Outcomes? Population-Level Analysis After 8 Years of a National HPV Vaccination Program in Australia

Yuill S et al. J Infect Dis 2020;222:499–508

Susan Yuill,[1,2,3] Sam Egger,[1] Megan Smith,[1,2,3] Louiza Velentzis,[1,2,3] C. David Wrede,[4,5] Deborah Bateson,[6,7] and Karen Canfell[1,2,3]

[1]Cancer Research Division, Cancer Council NSW, Sydney, Australia, [2]School of Public Health, University of Sydney, Sydney, Australia, [3]Melbourne School of Population and Global Health, University of Melbourne, Melbourne, Australia, [4]Department of Oncology & Dysplasia, Royal Women's Hospital, Melbourne, Australia, [5]Department of Obstetrics and Gynaecology, Melbourne Medical School, University of Melbourne, Melbourne, Australia, [6]Family Planning NSW, Sydney, Australia, [7]Discipline of Obstetrics, Gynaecology and Neonatology, The University of Sydney School of Medicine, Sydney, Australia

Background. Human papillomavirus (HPV) infection, and its sequelae of precancerous cervical lesions and their subsequent treatment, have been linked with an increased risk of adverse pregnancy outcomes. Publicly funded HPV vaccination of female adolescents began in Australia in 2007 with initial catch-up to age 26 years.

Methods. Using data from the National Perinatal Data Collection we compared rates of preterm births and small-for-gestational-age infants born in Australia 2000–2015. We used generalized linear models, assuming a Poisson distribution and log link function, with single-year categories of infant birth year, maternal age, and age-specific HPV vaccination coverage as independent variables.

Results. In maternal cohorts with 60%–80% HPV vaccination coverage as achieved in Australia, there was a relative rate reduction of 3.2% (95% confidence interval, 1.1%–5.3%) in preterm births and 9.8% (8.2% to 11.4%) in small-for-gestational-age infants, after adjustment for infant's birth year and maternal age.

Conclusion. This analysis provides provisional population-level evidence of a reduction in adverse pregnancy outcomes in cohorts of women offered HPV vaccination. Confounding by smoking or other variables and/or ecological analysis limitations, however, cannot be excluded. These findings indicate potential broader benefits of HPV vaccination than have been documented to date.

Oropharyngeal HPV prevalence in unvaccinated females, vaccinated females, and unvaccinated males aged 12–14 years, by vaccination status and HPV type

Columbia	88% (2012)	→	5% (2016)

Impact of HPV vaccine hesitancy on cervical cancer in Japan: a modelling study

Kate T Simms*, Sharon J B Hanley*, Megan A Smith*, Adam Keane, Karen Canfell

Summary

Background Funding for human papillomavirus (HPV) vaccination in Japan began in 2010 for girls aged 12–16 years, with three-dose coverage initially reaching more than 70%. On June 14, 2013, 2 months after formal inclusion in Japan's national immunisation programme, proactive recommendations for the HPV vaccine were suspended following reports of adverse events since found to be unrelated to vaccination, but which were extensively covered in the media. Vaccine coverage subsequently dropped to less than 1% and has remained this low to date. We aimed to quantify the impact of this vaccine hesitancy crisis, and the potential health gains if coverage can be restored.

Methods In this modelling study, we used the Policy1-Cervix modelling platform. We adapted the model for Japan with use of data on HPV prevalence, screening practices and coverage, and cervical cancer incidence and mortality. We evaluated the expected number of cervical cancer cases and deaths over the lifetime of cohorts born from 1994 to 2007 in the context of the vaccine hesitancy crisis. We assessed a range of recovery scenarios from 2020 onwards, including a scenario in which routine coverage is restored to 70%, with 50% catch-up coverage for the missed cohorts (aged 13–20 years in 2020). To estimate the impact of the vaccine crisis to date, we also modelled a counterfactual scenario in which 70% coverage had been maintained in 12-year-olds from 2013 onwards.

Findings The vaccine crisis from 2013 to 2019 is predicted to result in an additional 24 600–27 300 cases and 5000–5700 deaths over the lifetime of cohorts born between 1994 and 2007, compared with if coverage had remained at around 70% since 2013. However, restoration of coverage in 2020, including catch-up vaccination for missed cohorts, could prevent 14 800–16 200 of these cases and 3000–3400 of these deaths. If coverage is not restored in 2020, an additional 3400–3800 cases and 700–800 deaths will occur over the lifetime of individuals who are 12 years old in 2020 alone. If the crisis continues, 9300–10 800 preventable deaths due to cervical cancer will occur in the next 50 years (2020–69).

Interpretation The HPV vaccine crisis to date is estimated to result in around 5000 deaths from cervical cancer in Japan. Many of these deaths could still be prevented if vaccination coverage with extended catch-up can be rapidly restored.

Association between quadrivalent human papillomavirus vaccination and selected syndromes with autonomic dysfunction in Danish females: population based, self-controlled, case series analysis

BMJ 2020;370:m2930

Anders Hviid,[1,3] Nicklas M Thorsen,[1] Palle Valentiner-Branth,[2] Morten Frisch,[1,3] Kåre Mølbak[2,4]

869 patients with autonomic dysfunction syndromes from a cohort of 1,375,737 Danish born female participants aged 10 to 44 years during 2007-2016:

- 136 with chronic fatigue syndrome
- 535 with complex regional pain syndrome
- 198 with postural orthostatic tachycardia syndrome

Quadrivalent HPV vaccination did not statistically significantly increase the rate of a composite outcome of all syndromes with autonomic dysfunction in a 365 day risk period following vaccination (rate ratio 0.99, 95% CI 0.74 to 1.32) or the rate of any individual syndrome in the risk period:

- chronic fatigue syndrome (0.38, 95% CI 0.13 to 1.09)
- complex regional pain syndrome (1.31, 95% CI 0.91 to 1.90)
- postural orthostatic tachycardia syndrome (0.86, 95% CI 0.48 to 1.54)

Simon Harris T.D.
Minister of Health
Ireland

I am here to demonstrate my trust in HPV immunisation and how it protects women from developing cancer later in their lives.

We all know that the vaccine works and that it works very well.

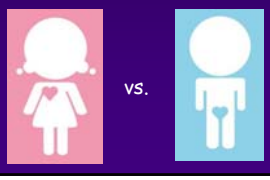
No serious side effects in any country can be scientifically attributed to this vaccine.

Thanks to the HPV vaccine, Ireland's daughters, mothers, wives, sisters and loved ones can live long and fulfilling lives without living in fear of cervical cancer.

I, as Minister of Health continue to pledge my full support to the HPV vaccination program and the tremendous work carried out by many people sitting here in this room today.

Wealth inequity

Gender inequity



Population pyramids and the number of people vaccinated through national HPV vaccination programmes by income (by the end of 2016)

(See the Editorial Commentary by Sanjose and Bruni, on pages 888–9.)

Background. Human papillomavirus (HPV) vaccination of girls with very high (>90%) coverage has the potential to eradicate oncogenic HPVs, but such high coverage is hard to achieve. However, the herd effect (HE) depends both on the HPV type and the vaccination strategy.

Methods. We randomized 33 Finnish communities into gender-neutral HPV16/18 vaccination, girls-only HPV16/18 vaccination, and hepatitis B virus vaccination arms. In 2007–2010, 11 662 of 20 513 of 40 852 of 39 420 resident boys/girls from 1992 to 1995 birth cohorts consented. In 2010–2014, cervicovaginal samples from vaccinated and unvaccinated girls at age 18.5 years were typed for HPV6/11/16/18/31/33/35/39/45/51/52/56/58/59/66/68. Vaccine efficacy for vaccinated girls, HE for unvaccinated girls, and the protective effectiveness (PE) for all girls were estimated. We extended the community-randomized trial results about vaccination strategy with mathematical modeling to assess HPV eradication.

Results. The HE and PE estimates in the 1995 birth cohort for HPV18/31/33 were significant in the gender-neutral arm and 150% and 40% stronger than in the girls-only arm. Concordantly, HPV18/31/33 eradication was already predicted in adolescents/young adults in 20 years with 75% coverage of gender-neutral vaccination. With the 75% coverage, eventual HPV16 eradication was also predicted, but only with the gender-neutral strategy.

Conclusions. Gender-neutral vaccination is superior for eradication of oncogenic HPVs.

Merck quadruples Gardasil supply in China contract but still might not meet full demand

by Angus Liu | Nov 12, 2018 10:38am

Supply to slowly grow in the short term, followed by steep ramp up from year 4-5

SAGE recommendations on HPV vaccination (October 2019)

In the context of a limited supply of HPV vaccine, SAGE recommended the following additional strategies:

1. All countries should temporarily pause implementation of boy, older age group (>15 years) and multi-age cohort (MAC) HPV vaccination strategies until vaccine supply allows equitable access to HPV vaccine by all countries.

2. To try to reach girls before they age out of the recommended primary target population, countries could target girls who are 13 or 14 years old or in the equivalent school grade for 2-dose vaccination

3. Countries could adopt an extended interval of 3-5 years between the 2 doses, with the first dose being given to younger girls

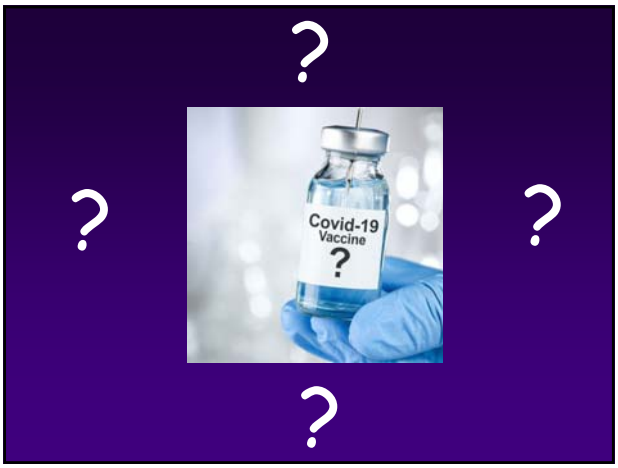
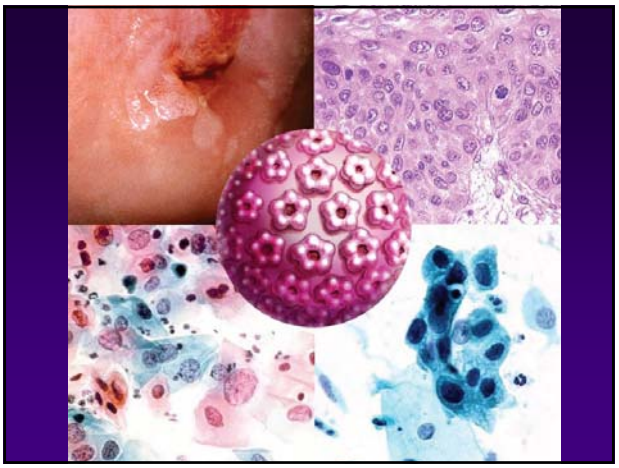
Conclusions (primary prevention)

in the 13 years since its introduction, HPV vaccination has seen many positive developments: a reduced number of doses and more flexible schedules have reduced cost and facilitated program implementation

2vHPV, 4vHPV and 9vHPV vaccines are extremely safe, highly effective but underused (especially in males and only exceptionally used in HIV+ individuals)

as both genders are responsible for HPV transmission, both genders should get vaccinated to share the burden in reducing the risk of HPV-related disease, as well as have equal access to direct vaccine benefits





Conclusions GENERAL

the magnitude of prevention potential of HPV-related cancers is currently not rivalled for any other neoplastic disease in humans

only integration of primary and secondary prevention brings efficieny benefits

HPV-based screening is beneficial over cytology-based screening

only gender-neutral vaccination will lead to control of HPV-related diseases in both genders and maximize prevention of cervical cancer

failure to implement HPV-based screening and gender-neutral, age-extended and global HPV vaccination looks like a missed public health opportunity

several pre-COVID-19 and COVID-19-related problems arrising

GIVE LOVE NOT HPV

We know HPV is causing cervical cancer

We have excellent HPV screening tests and HPV vaccines

We can envisage cervical cancer elimination

Although we are in a COVID-19 pandemic,

we are also in an HPV pandemic!

Tackling cervical cancer in Europe amidst the COVID-19 pandemic

Arbyn M, Bruni L, Kelly D, Basu P, Poljak M, Gultekin M, Bergeron C, Ritchie D, Weiderpass E
Tackling cervical cancer in Europe amidst the COVID-19 pandemic.
Lancet Public Health 2020; 5: e425.

the COVID-19 pandemic might also generate opportunities for more efficient prevention, by promoting more cost-effective, evidence-based protocols, by focusing on women who are at high-risk, extending HPV testing on self-collected samples, and discouraging inefficient policies, such as screening with two tests.
